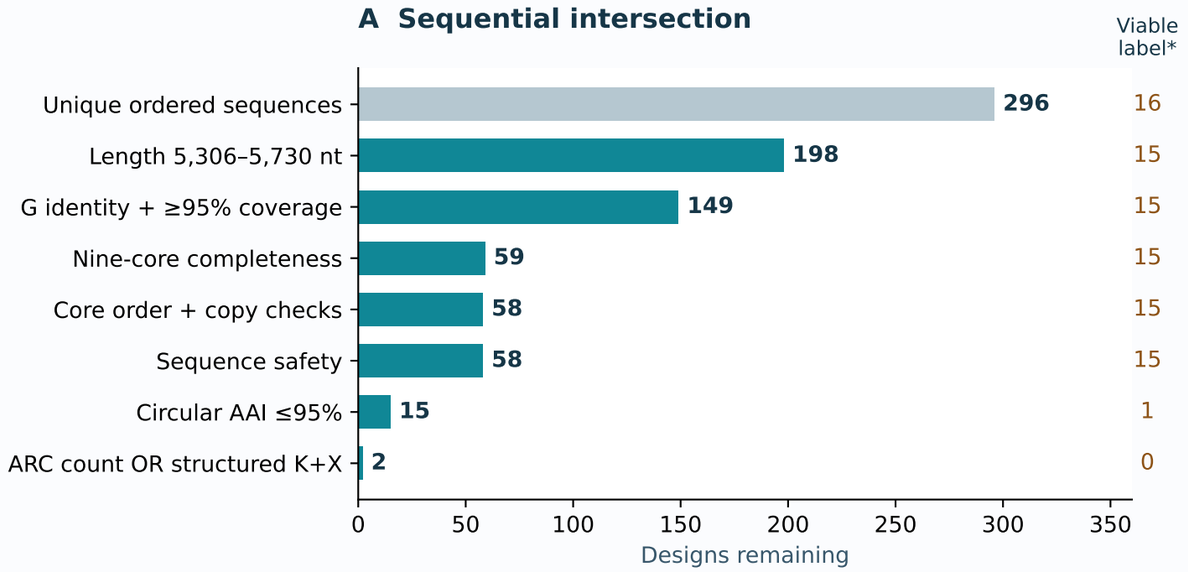
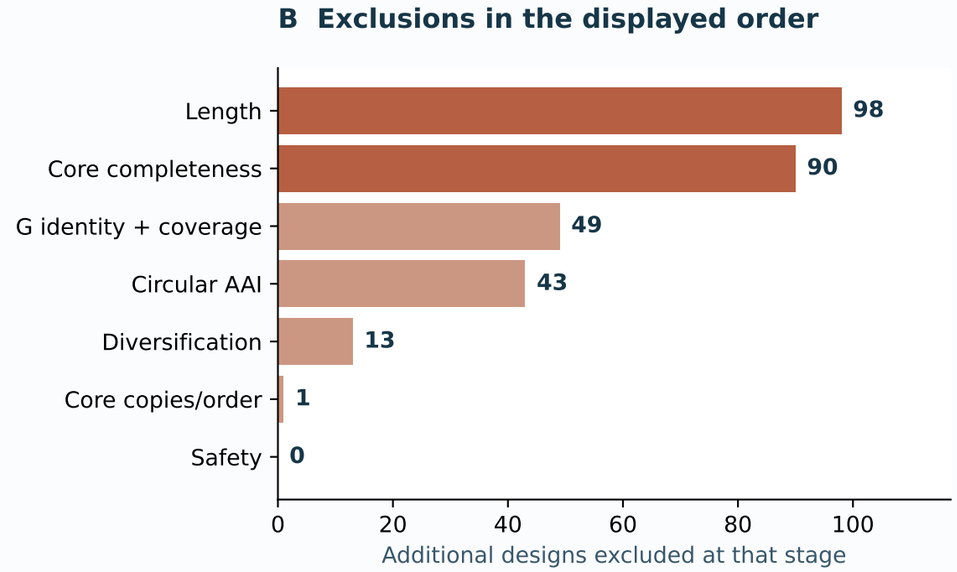
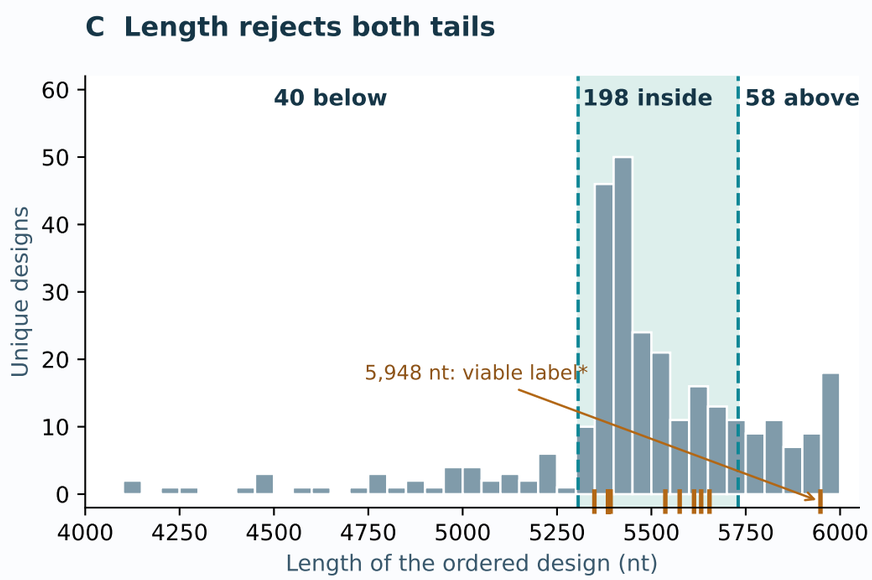
Why ARC’s selected designs fail our combined screen

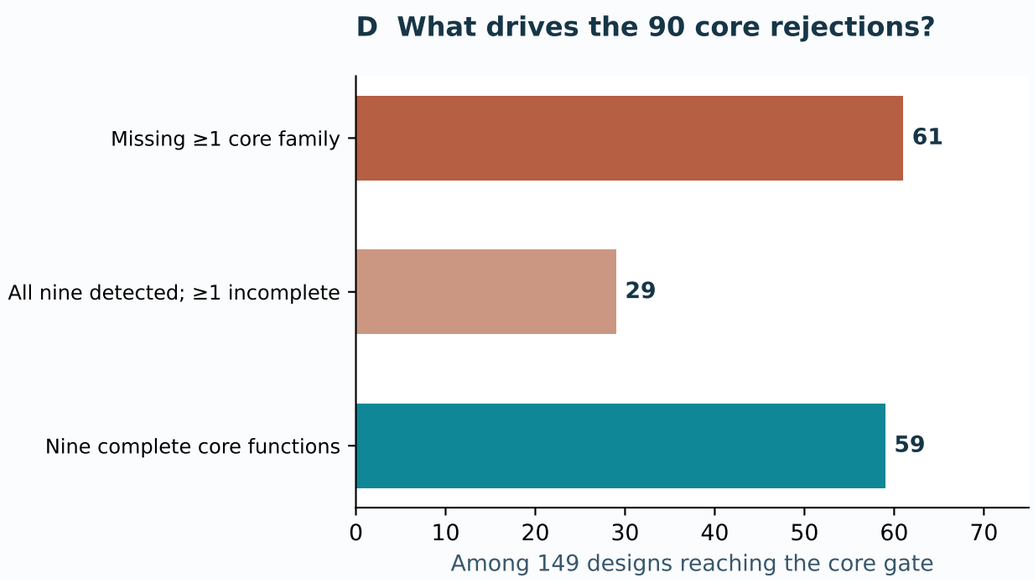
Largest sequential losses: length −98, core completeness −90; safety excludes none

302 ordered records → 296 unique sequences for this audit • selected-cohort attrition, not a generation pass rate









The later core copy/order gate rejects one extra-core-copy design; no additional order violation was observed in those 59 designs.

*Viable label includes acquired mutations during rebooting. Both final passers are labeled nonviable. Screening is not a bootability prediction.

Independent, measured-only AAI: 106 / 198 fail. Downstream tests were not run on every early rejection, so independent counts do not sum.

Separate length-relaxed diagnostic: the 5,948-nt design also passes core/safety; all 16 viable-labeled designs pass those constraints.
